

PLSC 504 – Fall 2023

Causal Inference with Observational Data

September 20, 2023

What We're On About

Here:

- Y is the outcome of interest,
- W is the primary predictor / covariate ("treatment") of interest,
- T_i is the "treatment indicator" for observation i ,
- We're interested in estimating τ , the "treatment effect" of W on Y ,
- \mathbf{X} are observed confounders,
- \mathbf{U} are unobserved confounders.

- **Randomize**

(or...)

- Instrumental Variables Approaches
- Selection on Observables:
 - Regression / Weighting
 - Matching (propensity scores, multivariate/minimum-distance, genetic, etc.)
- Regression Discontinuity Designs (“RDD”)
- Differences-In-Differences (“DiD”)*
- Synthetic Controls*
- Others...

* We'll discuss these approaches in a couple weeks, as models for panel/time-series cross-sectional data.

Under Randomization

Note:

- Randomized assignment of W “balances” covariate values – both observed and unobserved – *on average*...
- That is, under randomization of W :

$$E(\mathbf{X}_i, \mathbf{U}_i \mid W_i = 0) = E(\mathbf{X}_i, \mathbf{U}_i \mid W_i = 1)$$

or, more demandinglly,

$$E[f(\mathbf{X}, \mathbf{U}) \mid W_i = 0] = E[f(\mathbf{X}, \mathbf{U}) \mid W_i = 1]$$

- Can yield imbalance by random chance...

Covariate Balance / Imbalance

Balanced X

Unbalanced X

Covariate Imbalance Under Randomization

Why seek balance when randomizing?

- More accurate estimates of treatment effects
- Higher statistical power

Possible Approaches:

1. Force balance by design:

- Stratification / blocking
- Matching / paired randomization (see below)
- Rerandomization approaches (e.g., [Morgan and Rubin 2012](#))

2. Post-randomization analysis:

- Pre- vs. post-treatment Y values / “gain scores”
- (Post-treatment) stratification by \mathbf{X}
- (Pre-treatment) covariate adjustment via weighting / regression

Nonrandom Assignment of W_i

Valid causal inference requires $Y_{0i}, Y_{1i} \perp W_i | \mathbf{X}_i, \mathbf{U}_i$

- That is, treatment assignment W_i is *conditionally ignorable*

“What if I have unmeasured confounders?”

- In general, that's a bad thing.
- One approach: obtain *bounds* on possible values of τ
 - Assume you have one or more unmeasured confounders
 - Undertake one of the methods described below to get $\hat{\tau}$
 - Calculate the range of values for $\hat{\tau}$ that could occur, depending on the degree and direction of confounding bias
 - Or ask: How strong would the effect of the \mathbf{U} s have to be to make $\hat{\tau} \rightarrow 0$?
- Some useful cites:
 - Rosenbaum and Rubin (1983)
 - Rosenbaum (2002)
 - DiPrete and Gangl (2004)
 - Liu et al. (2013)
 - Ding and VanderWeele (2016)

Digression: Instrumental Variables

Instrumental Variables

As in the more general regression case where we have $\text{Cov}(\mathbf{X}, u) \neq 0$, instrumental variables can be used to address confounding in causal analyses.

Instrumental Variables (continued)

Considerations:

- Requires:
 1. $\text{Cov}(\mathbf{Z}, W) \neq 0$
 2. \mathbf{Z} has no independent effect on Y , except through W (“exclusion restriction”)
 3. \mathbf{Z} is exogenous [i.e., $\text{Cov}(\mathbf{Z}, \mathbf{U}) = 0$]
- Arguably most useful when [treatment compliance is uncertain](#) / driven by unmeasured factors (“[intent to treat](#)” analyses)
- Mostly, they’re not that useful at all...
 - [Bound et al. \(1995\)](#): Weak instruments are worse than endogeneity bias
 - [Young \(2021\)](#): Inferences in published IV work (in economics) are wrong and terrible
 - [Shalizi \(2020, chapters 20-21\)](#): Gathers all the issues together, sometimes hilariously
- Other useful references:
 - [Imbens et al. \(1996\)](#) (the overly-cited one)
 - [Hernan and Robins \(2006\)](#) (making sense of things)
 - [Lousdal \(2018\)](#) (a good intuitive introduction)

Nonrandom Assignment of W_i (continued)

So...

- Causal inference with observational data typically requires that $\mathbf{U} = \emptyset$...
- This typically requires a strong theoretical motivation in order to assume that the observed \mathbf{X} exhausts the list of possible confounders.
- **Even if** this assumption is reasonable, there are two (related) important concerns:
 - Lack of *covariate balance* (as above)
 - Lack of *overlap* among observations with $W_i = 0$ vs. $W_i = 1$
 - The latter is related to *positivity*, the requirement that each observation's probability of receiving (or not receiving) the treatment is greater than zero

Overlap

Complete Overlap

Moderate Overlap

No Overlap

In general:

- Ensuring overlap allows us to make counterfactual statements from observational data
 - Requires that we have comparable $W_i = 0$ and $W_i = 1$ units
 - It's *necessary* – no overlap means any counterfactual statements are based on assumption
 - Think of this as an aspect of *model identification* (Crump et al. 2009)
 - Most often handled via matching
- Ensuring covariate balance corrects potential bias in $\hat{\tau}$ due to (observed) confounding
 - This can be done a number of different ways: stratification, weighting, regression...
 - Key: Adjusting for (observable) differences across groups defined by values of W
- In general, we usually address overlap first, then balance...

Matching is a way of dealing with one or both of covariate overlap and (im)balance.

The process, generally:

1. Choose the \mathbf{X} on which the observations will be matched, and the matching procedure;
2. Match the observations with $W_i = 0$ and $W_i = 1$;
3. Check for balance in \mathbf{X}_i ; and
4. Estimate $\hat{\tau}$ using the matched pairs.

Variants / considerations:

- 1:1 vs. 1:k matching
- “Greedy” vs. “Optimal” matching (see [Gu and Rosenbaum 1993](#))
- Distances, calipers, and “common support”
- Post-matching: Balance checking...

- Simplest: Exact Matching

- For each of the n observations i with $W = 1$, find a corresponding observation j with $W = 0$ that has identical values of \mathbf{X}
- Calculate $\hat{\tau} = \frac{1}{n} \sum (Y_i - Y_j)$
- Generally not practical, especially for high-dimensional \mathbf{X}
- Variants: “coarsened” exact matching (e.g., [Iacus et al. 2011](#))

- Multivariate Matching

- Match each observation i which has $W = 1$ with a corresponding observation j with $W = 0$, and whose values on \mathbf{X}_j are the most similar to \mathbf{X}_i
- One example: Mahalanobis distance matching, based on the distance:

$$d_M(\mathbf{X}_i, \mathbf{X}_j) = \sqrt{(\mathbf{X}_i - \mathbf{X}_j)' \mathbf{S}^{-1} (\mathbf{X}_i - \mathbf{X}_j)}.$$

Flavors of Matching (continued)

- Propensity Score Matching
 - Match observation i which has $W = 1$ with observation j having $W = 0$ based on the closeness of their *propensity score*
 - The propensity score is, $\Pr(W_i = 1|\mathbf{X}_i)$, typically calculated as the predicted value of T_i (the treatment indicator) from a logistic (or other) regression of T on \mathbf{X} .
 - The assumptions about matching [that Y is orthogonal to $W|\mathbf{X}$ and that $\Pr(W_i = 1|\mathbf{X}_i) \in (0, 1)$] mean that $Y \perp W | \Pr(T|\mathbf{X})$.
 - In practice: [read this...](#)
- Other variants: Genetic matching ([Diamond and Sekhon 2013](#)), etc.¹

¹[Shalizi \(2016\)](#) notes that “(A)pproximate matching is implicitly doing nonparametric regression by a nearest-neighbor method,” and that “(M)aybe it is easier to get doctors and economists to swallow “matching” than “nonparametric nearest neighbor regression”; this is not much of a reason to present the subject as though nonparametric smoothing did not exist, or had nothing to teach us about causal inference.”

Interestingly, quite a few of the good matching programs written for R have been written by political scientists...

- the `Match` package (does propensity score, M -distance, and genetic matching, plus balance checking and other diagnostics)
- the `MatchIt` package (for pre-analysis matching; also has nice options for checking balance)
- the `optmatch` package (suite for 1:1 and 1: k matching via propensity scores, M -distance, and optimum balancing)
- `matching` (in the `arm` package)

Regression Discontinuity Designs

“RDD”:

- Treatment changes abruptly [usually at some threshold(s)] according to the value(s) of some measured, continuous, pre-treatment variable(s)
 - This is known as the “assignment” or “forcing variable(s),” sometimes denoted **A**
 - Formally:

$$T_i = \begin{cases} 0 & \text{if } A_i \leq c \\ 1 & \text{if } A_i > c \end{cases}$$

- Intuition: Observations near but on either side of the threshold(s) are highly comparable, and can be used to (locally) identify τ
- This is because variation in T_i near the threshold is effectively random (a “local randomized experiment”)
- E.g. [Carpenter and Dobkin \(2011\)](#) (on the relationship between the legal drinking age and public health outcomes like accidental deaths)

RDD (continued)

- Pluses:
 - Can be estimated straightforwardly, as:
$$Y_i = \beta_0 + \beta_1 A_i + \tau T_i + \gamma A_i T_i + \epsilon_i$$
 - Generally requires fewer assumptions than IV or DiD (and those assumptions are easier to observe and test)
- Minuses:
 - Provides only an estimate of a local treatment effect
 - Fails if (say) subjects can manipulate A in the vicinity of c
- [Lee and Lemieux \(2010\)](#) is an excellent (if fanboi-ish) review
- R packages: `rddtools`, `rdd`, `rdrobust`, `rdpower`, `rdmulti`

- R
 - Packages for matching are listed above (*Matching*, *MatchIt*, etc.)
 - Similarly for RDD (*rddtools*, *rdd*, etc.)
 - IV regression: *ivreg* (in *AER*), *tsls* (in *sem*), others
 - See generally the *Econometrics* and *SocialSciences* CRAN Task Views
- Stata also has a large suite of routines for attempting causal inference with observational data
- And there's a pretty good NumPy/SciPy-dependent package for Python, called (creatively) *CausalInference*

Example: Sports and Grades in High School

Question: Does participation in high school varsity sports help or hinder academic achievement (i.e., grades)?

Data: “High School And Beyond” survey (1983 wave) ($N = 1375$)

Variables:

- grades: As=4, As & Bs=3.5, etc.
- sports: 1 if participated in varsity sports, 0 otherwise
- fincome: Family income (7-point scale)
- ses: Socioeconomic Status: 1=low, 2=middle, 3=high
- workage: Age at which started working
- hmwktime: Time spent on homework (7-point scale)*
- female: 1 = female student, 0 = male student
- academic: 1 if the student is on an academic track, 0 else
- remedial: 1 if the student took ≥ 1 remedial course
- advanced: 1 if the student took ≥ 1 advanced course

* Likely post-treatment, so we'll omit in the examples below.

F-statistic: 51.2 on 8 and 1366 DF, p-value: <2e-16

Balance Tests (Pre-Matching)

These are P -values associated with t -tests (for binary predictors) or Kolmogorov-Smirnov tests (for continuous predictors) for balance between `sports = 0` and `sports = 1`.

Exact Matching

```
> M.exact <- matchit(sports~fincome+ses+workage+female+academic+  
+ remedial+advanced,data=sports,method="exact")  
> M.exact
```

Call:

```
matchit(formula = sports ~ fincome + ses + workage + female +  
academic + remedial + advanced, data = sports, method = "exact")
```

Exact Subclasses: 166

Sample sizes:

	Control	Treated
All	864	511
Matched	287	239
Unmatched	577	272

```
> # Output matched data:
```

```
> sports.exact <- match.data(M.exact,group="all")
```

```
> dim(sports.exact)  
[1] 526 12
```

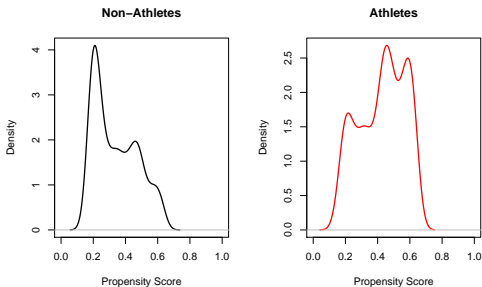

Exact Matching: Balance

These are P -values associated with t -tests (for binary predictors) or Kolmogorov-Smirnov tests (for continuous predictors) for balance between $\text{sports} = 0$ and $\text{sports} = 1$. Black dots are pre-matching; green triangles are after exact matching.

Propensity Score Matching

```
> PSfit <- glm(sports~fincome+ses+workage+female+academic+remedial+  
+             advanced,data=sports,family=binomial(link="logit"))  
  
> # Generate scores & check common support:  
  
> PS.df <- data.frame(PS = predict(PSfit,type="response"),  
+                      sports = PSfit$model$sports)
```

Propensity Score Matching

```
> M.prop<-matchit(sports~fincome+ses+workage+female+academic+
+                 remedial+advanced,data=sports,
+                 method="nearest")
> summary(M.prop)
```

```
.
.
.
```

Percent Balance Improvement:

	Mean Diff.	eQQ Med	eQQ Mean	eQQ Max

Some Questions...

- What – if anything – can the general robustness of our results tell us about the relationship between varsity athletics and grades?
- What can they tell us about our model?
- What mechanism(s) / circumstances might allow us to investigate the relationship between varsity athletic participation and grades using an RDD?
- What circumstances – if any – might allow us to investigate this relationship using instrumental variables?
- What sort(s) of experiments – natural or otherwise – might allow us to investigate this same relationship?
